

The GitHub API does appear to be RESTful. My reasoning for this is that several required features of RESTful can be observed through postman and lead me to believe all factors are met for it to be a REST API. The interaction between client and server is simplified, I at no point needed to be concerned about how the server works beyond the known uniform interface. In addition to this, I was unable to determine which server I was accessing for information through these basic requests. Lastly, the process was stateless as was indicated through the verb restrictions on each test. Lastly, the URL calling after declaring which verb was to be used while in postman followed expected naming conventions and avoided the use of question-mark queries within the URL header.
